Dear Cresta team,

I built a working contact-center AI economics calculator for Cresta's Growth Marketer role. It turns an evaluation-stage search question into a tool a buyer can use: change assumptions, see when handoffs erase savings, and export a scenario for discussion with finance. It separates released capacity from cash savings and makes the limits explicit.
Open the interactive calculator

That is how I approach organic growth: understand the buyer's decision, build something useful, then make it discoverable and measurable. At SeeScan, I own web operations across three technical-product sites. My work connects product and support content, search findability, GA4/GTM reporting and verified releases with product, engineering and DevOps.

I have also built the request workspace, reporting system and shared wiki that keep that work moving. At Los Bravos, I carried client research into bilingual market materials and a searchable business-development workspace.

For Cresta, I would bring that combination of commercial thinking and hands-on implementation to SEO, AI discovery and experimentation. The calculator is a working example of what I can build; its modeled results are not claims of customer savings or acquired pipeline.

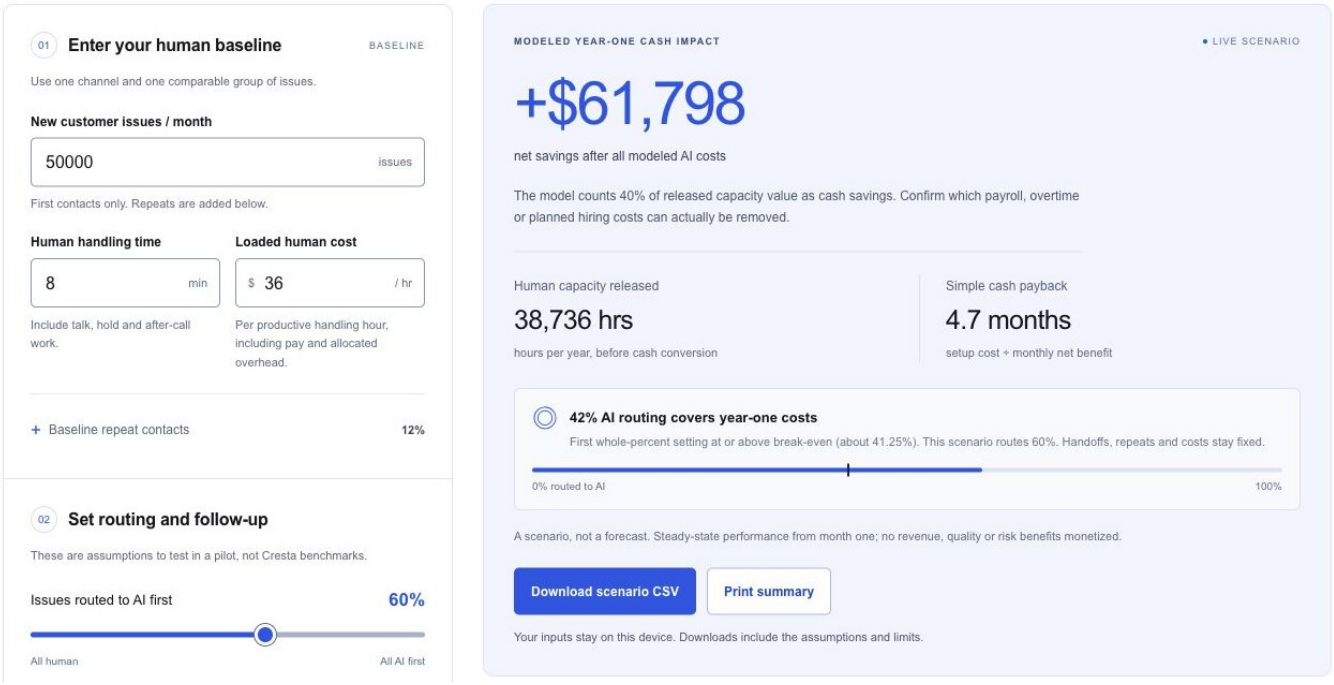

Thank you for considering my application.

Sebastian Becerra

Contact center AI economics explorer

Working application sample by Sebastian Becerra • Fictional scenarios

I built this tool around a buyer's evaluation question: when does contact-center AI pay for itself? It compares human handling costs with AI usage, recurring fees and setup while accounting for handoffs and repeat contacts. Its purpose is to help an operations leader and finance reviewer test the same assumptions before a vendor conversation.

Actual runnable interface. All example values are fictional; no Cresta pricing or customer outcomes are assumed.

Try the decision rather than just the headline

Start with the default scenario: $61,798 modeled first-year net cash benefit and 4.7-month simple payback. Increase the handoff rate from 20% to 30% and the result becomes a $18,726 cash cost. Choose Capacity only and the 38,736 annual hours released remain, but with no cash realization the first-year cash cost is $496,000.

All twelve assumptions are editable. The tool recalculates the cost comparison, work distribution, routing break-even and handoff sensitivity. Download scenario CSV captures inputs, results and limitations; Print summary creates a readable report. Invalid inputs are flagged before export. Calculations run locally with no account, data upload or analytics.

How it supports organic acquisition

The content addresses contact-center AI cost and ROI evaluation intent, explains its model in readable HTML and connects to Cresta's demo page. It is a candidate application sample, not a live acquisition program. Search reach, AI citations, qualified demos and pipeline contribution would require instrumentation and measurement after an approved deployment.

Built with AI assistance under my direction. The model assumes steady performance from month one and excludes ramp, staffing constraints, contract tiers, later repeat chains, and monetized quality or risk effects. Its transparency is deliberate: a buyer should be able to challenge the result.

Operating the website behind the buyer journey

Existing work at SeeScan • Digital Content Specialist (Web, Content & Analytics)

I own web operations across SeeScan, DeepSea and SeeSnake Support. The business need is continuity: buyers need accurate product information, customers need usable documentation, and each release can change both. I built tools and processes that connect that work to implementation and measurement.

From business request to production

Digital Desk structures requests by brand, priority, affected page and business context. I use that information with GitLab issues, merge requests and a shared wiki to coordinate changes with product, engineering and DevOps. Production approval and deployment involve the responsible engineering and DevOps partners.

A July 2026 support release shows the work reaching customers. I delivered new microREEL DSL and microDRAIN DSL support pages, aligned related APX Via kit content and updated manual links. The work record connects the July 8 promotion request to production verification on July 15. The result is a documented customer-facing release, with related product and support information kept together.

Organic discovery and trustworthy measurement

I improved the structure and findability of the support knowledge base through consistent terminology, search metadata and a consolidation plan for overlapping content. Analytics HQ connects GA4/GTM measurement across the three properties with scheduled reporting, metric definitions, freshness checks and data-quality controls. That gives web decisions a reporting process that can be maintained after an individual change ships.

Knowledge that supports execution

The shared wiki links products, website environments, responsibilities, delivery history and reporting. It also supplies reusable context for AI-assisted work. I review outputs against source records and correct inaccurate assumptions before they become operating guidance.

Why this matters for Cresta

This is the operating discipline behind an organic program: turn buyer questions into useful content, ship changes safely, preserve product accuracy and make the resulting signals interpretable. The evidence establishes implemented systems and verified releases. It does not isolate revenue, pipeline or conversion lift from those changes.

Evidence basis: dated SeeScan operating records, including the July release and September 23, 2026 work-record export. Internal addresses and access details are omitted.
